

Phase 17: prospect memory in PostgreSQL

Prospect rows, clip metadata, and factory batches are stored in the existing Bliss database. There is no second database. Video files and QR files stay on disk. The suite result is 268 passed, 0 failed, 0 skipped. This is not a measurement of 100, 1,000, or 10,000 prospects.

The development library reports Prospect memory: POSTGRESQL. One database. Media files stay on disk. Mesa Norte and Puerto Azul are separate rows. Puerto Azul stays preserved and suppressed. Delivery stays NOT_SENT. The businesses on example.com are fixtures.

MEDIA FUEL

Source slices

Upload about 15 seconds of video Alpha is allowed to use. The library counts a clip only when it is unique, usable, and qualified. Bots reuse that slice. They do not ask for a new cut for every prospect.

Prospect memory: POSTGRESQL. One database. Media files stay on disk.

ADVERTISER DISCOVERY

Score a prospect before a demonstration

Record the business name and the public page where it was found. A named business from a public source is kept even when the road is not ready for a demonstration. A demonstration will wait for a score of 100. Nothing is sent
